pet	blue	green	red	Row Total
cat	$P(\text{cat})P(\text{blue})$	$P(\text{cat})P(\text{green})$	$P(\text{cat})P(\text{red})$	$P(\text{cat})$
dog	$P(\text{dog})P(\text{blue})$	$P(\text{dog})P(\text{green})$	$P(\text{dog})P(\text{red})$	$P(\text{dog})$
Column Total	$P(\text{blue})$	$P(\text{green})$	$P(\text{red})$	1

All of the information is in the margins!

Cell probabilities can be calculated from the marginal probabilities.

# Why do we care about independence?

Conditional probabilities are at the heart of predictions.

Independence of variables A & B

no point in making a prediction of A from B

# Practice Problems

**HINT: USE THE TABLE OF CELL, ROW, COLUMN, & MARGINAL PROBABILITIES.**

- 1. Create an empty table**
- 2. Fill in the information provided in the question**
- 3. Identify the requested probability**
- 4. Use the rules of probability to fill-in the gaps in the table to calculate the probability in question**

Q:

If 44% of college students have access to Netflix, 35% have access to Hulu, and 20% have access to both, then what is the probability that a randomly selected student has either Hulu or Netflix?

<b>Product</b>	<b>Apple OS</b>	<b>Windows OS</b>	
Laptop	a	b	.80
Desktop	c	.15	d
	.60	e	f

**Q:**

Suppose the table of probabilities described the computer type and operating system choices for the Vanderbilt student population.

Calculate

- $P(\text{Apple OS} \mid \text{Laptop})$
- $P(\text{Laptop} \mid \text{Apple OS})$
- $P(\text{Laptop and Apple OS})$

Q:

Is computer type and computer operating system independent in the population from the previous question?

Q:

Suppose three machines generate widgets with a defect rate of 0.1, 0.01, and 0.001, respectively. If the machines generate the same number of widgets, what is the probability that a randomly selected widget is defective.

Q:

Machines A, B, and C generate widgets with a defect rate of 0.1, 0.01, and 0.001, respectively. If machine A generates twice as many widgets as B, and machine B generates twice as many widgets as machine C, what is the probability that a randomly selected widget is defective.

Q:

Machines A, B, and C generate widgets with a defect rate of 0.1, 0.01, and 0.001, respectively. Machine A generates twice as many widgets as B, and machine B generates twice as many widgets as machine C. If a randomly selected widget is defective, what is the probability that the widget came from machine A?

# Q:

Suppose there are 5 coins, 4 of which are fair and one with  $P(\text{tails}) = .25$ . A coin is randomly selected and flipped 3 times. Calculate the following:

- $P(\text{fair coin selected} \mid \text{flip sequence} = \text{TTT})$
- $P(\text{2 heads in 3 flips} \mid \text{biased coin selected})$
